Date of Deposit: January 2, 2001

#### FIELD OF THE INVENTION

The present invention relates to the field of information systems. More specifically, the present invention relates to simplified access to online services, including access with roaming capabilities.

#### BACKGROUND OF THE INVENTION

The Internet is a well-known collection of public and private data communication and multimedia networks that operate using common protocols to form a world wide network of networks. Recently there has been an explosion in the availability of online services, e.g., online commerce sites, email sites, news information sites, and so forth, all reachable over the Internet. This rapid growth is due, in part, to the availability of fast, reliable and affordable computing device systems and the general simplification of networking hardware and configuration. Thus, consumers and businesses alike now have access to hardware that makes effective online commerce commercially practicable.

To access these online services, an online service provider typically sets up a home page (e.g., "web site") on the World Wide Web, which is a logical overlay of the Internet. Simply, web sites are machines located someplace within the Internet with traditional naming conventions for the machines, e.g., named WWW, and holding themselves available to interact using standard protocols such as Hypertext Transfer Protocol (HTTP), and programming languages or environments such as Hypertext

Transfer Protocol HTML, XML, Java, JavaScript, Java Beans, ActiveX, Visual Basic, or the like.

To access a service via a web site, a user executes a "browser," such as the Internet Explorer, Netscape Navigator, or other network aware application program that is configured to communicate with an online service provider's web site. The user locates a particular online service provider, and proceeds to logon to the web site (or equivalent) to access and utilize the service. At this point, the user must enter their logon identification (Id), password, and other data sufficient to identify the user and allow access of the user to the service.

As the user accesses several services, the user is required to maintain several logon identification and passwords. For example, a user may request to access several services such as Hotmail® for email services, HomeGrocer.com® for home delivered groceries, Washington Mutual Bank™ for online banking, and so forth.

Often times, in order to keep track of the different logon lds and passwords, a user may try to use a common logon ld, such as "Justin", and password for several services. However, more than likely, a logon ld for one service is rejected by another service because of the likelihood that some other user would have the same logon ld is high unless one constructs an arbitrary user ld. In that case, the user ld is difficult to remember and user unfriendly. Depending on the number of services utilized by the user, the user may be required to have and manage numerous different logon lds and passwords.

One known method for managing the several different logon lds and passwords is to store this information within the computer or device for accessing the various

services. However, because this information is stored within the device, if the device is altered and/or loses its memory or the user roams to different devices, the user is required to repeat the process of setting up the several logon lds and passwords in order to access the different services again. Further, the user would not have access to his/her configuration information.

Thus, what is needed is an environment that provides a user the ability to access online services requiring logon lds and passwords and roam from one device to another without having to manage several logon lds and passwords, nor several sets of configuration information.

#### BRIEF DESCRIPTION OF DRAWINGS

The present invention is illustrated by way of example and not by way of limitation in the figures of the accompanying drawings, in which the like references indicate similar elements and in which:

Figure 1 illustrates a user 100 accessing several online services through a network 104, in accordance with one embodiment of the invention;

Figure 2 illustrates an online service provider utilized by a user to access several online services without having to provide logon identifications and passwords for each of the online service, in accordance with one embodiment of the invention;

Figures 3a and 3b illustrate an alternate embodiment of the invention where one or more users from selected ones of different clients may access and utilize one or more online services through an online service provider (i.e. with roaming capability) without having to manage several logon identifications and passwords, and configurations, in accordance with the invention;

Figure 4 is a flow chart according to one embodiment of the invention, illustrating a client subscribing with an online service provider for accessing one or more online services without the need for managing several logon identifications and passwords, and configurations, with the roaming capability;

Figure 5 illustrates the operational flow of the relevant aspects of the online service provider 102 facilitating access to online services and roam from one device to another without having to manage several logon identifications and passwords, and configurations; and

Figure 6 illustrates an example server suitable for use for online service provider 102 of Fig. 1, in accordance with one embodiment.

# DETAILED DESCRIPTION OF THE INVENTION

In the following description, various aspects of the invention will be described. However, it will be apparent to those skilled in the art that the invention may be practiced with only some or all aspects of the invention. For purposes of explanation, specific numbers, materials and configurations are set forth in order to provide a thorough understanding of the invention. However, it will also be apparent to one skilled in the art that the invention may be practiced without the specific details. In other instances, well known features are omitted or simplified in order not to obscure the invention.

Parts of the description will be presented using terms such as end-user interfaces, buttons, and so forth, commonly employed by those skilled in the art to convey the substance of their work to others skilled in the art. Parts of the description will be presented in terms of operations performed by a computing device, using terms such as submitting, requesting, selecting, confirming and so forth. As well understood by those skilled in the art, these quantities and operations take the form of electrical, magnetic, or optical signals capable of being stored, transferred, combined, and otherwise manipulated through mechanical and electrical components of a digital system. The term digital system includes general purpose as well as special purpose computing machines, systems, and the like, that are standalone, adjunct or embedded.

Various operations will be described in turn in a manner that is most helpful in understanding the invention, however, the order of description should not be construed as to imply that these operations are necessarily order dependent. Furthermore, the

phrase "in one embodiment" will be used repeatedly, however the phrase does not necessarily refer to the same embodiment, although it may.

In various embodiments of the invention, a user is able to access online services requiring logon configurations and roam from one device to another without having to manage several logon configurations.

Figure 1 illustrates a user 100 accessing several online services through a network 104, in accordance with one embodiment of the invention. In Fig. 1, the user 100 is in communication, via a client 101 with a network 104. Also attached to the network 104 is an online service provider 102 to provide online services, such as an unique email address service 110 (U.S. Patent Application serial no. 09/504,236) and billing masking service 111 (U.S. Patent Application serial no. 09/553,068).

It is assumed that the client **101** comprises a computing device, such as a personal computer, which operates on behalf of the user **100** (a subscriber to online service provider **102**). In alternate embodiments, the client **101** may be incorporated into an electronic card, a telephone, a personal digital assistant (PDA), a portable audio device, a portable audiovisual device, a cellular telephone, a key-chain dongle, or within an automobile or other transportation device.

Also shown in **Fig. 1**, the online service provider **102** is in communication with the user **100**, via the client **101**, through the network **104**, in accordance with the invention. The user **100** subscribes to the online service provider **102**, via the client **101**, through any number of subscription processes known in the art. The user **100** may be charged a fee for allowing the user to access the online services **110-111**. This subscription data is received by the online service provider **102**, where the online

services 110-111 without having to manage a logon Id and password pair. Simplified access and utilization of the online services 110-111 is facilitated by the online service provider 102 associating an identifier with the user 100 and his/her subscribed online services 110-111, for example, a globally unique identifier (GUID), in accordance with the invention. Generation of identifiers such as GUIDs, which may involve adding a date and time to a serial number of a device in a client, is known, and accordingly, will not be discussed further. As a result, a user is able to access several online services through an online service provider without having to manage a logon Id and password pair.

Moreover, the invention provides an approach to allow the configuration information (such as the user's subscribed online services and the user's preference settings) of the user to be available, even if the user accesses the online service from different devices (to be described more fully below).

Figure 2 illustrates an online service provider utilized by a user to access several online services without having to provide logon Id and password, in accordance with one embodiment of the invention. In the one embodiment illustrated in Fig. 2, in order to subscribe with the online service provider 102, the user 100 communicates with a web site 201 of the online service provider 102 through a browser application program 202 of the client 101.

The subscription data may include user information such as name, address, phone number, and the various online services (such as the unique email address service, billing masking service) the user is interested in. As the user **100** subscribes to

these online services with the online service provider 102, the web site 201 of the online service provider 102 generates an identifier corresponding to the user 100, for example, a GUID 203 associated with the client 101 and the user 100. The subscription data and the GUID 203 is received at the online service provider 102. Furthermore, the web site of the service provider 102 deposits the GUID 203 within the client 101. Depositing of the GUID 203 within the client 101 may be in any form known in the art such as, but not limited to, a "cookie" 205 stored on the browser application program 202 of the client 101. Subsequently, when the user 100 communicates with the web site 201 of the online service provider 102 through the browser application program 202 (such as Internet Explorer) with the deposited GUID 203, the online service provider 102 may be provided with the GUID 203.

Once the user 100 subscribes to the various services of the online service provider 102, the online service provider 102 associates the received GUID 203 with the user 100, which in turn associates GUID 203 with the one or more subscribed online services 110-111. The number of online services 110-111 associated with the GUID 203 will depend upon the number of online services the user selects to subscribe, for example, the user 100 may select to subscribe to both online services 110-111 shown, in which case, the online service provider 102 will associate the GUID 203 with user 100 and both of the online services 110-111.

Illustrated in **Fig. 2**, is a data structure suitable for use to store data for facilitating access to several online services by the online service provider **102**. The data structure may be a table **210** including a number of columns **212-214** for storing various information associated with the user **100**, such as but not limited to, a user's

subscription information 212, a GUID of a client 211, and the online services that a user has selected to access through the online service provider 214. As shown in table 210, the GUID 203 is associated with the user and his/her selected services 110-111.

The table **210** is illustrated as a single table for ease of understanding. As those skilled in the art will appreciate, a data structure involving multiple tables as well as other non-tabular data structures may be employed for storing various data regarding user information.

As a result, when the user requests access to an online service by communicating with the web site 201 of the online service provider 102 through the browser application program 202 of the client 101, the online service provider 102, receives the deposited GUID 203, e.g., within the "cookie" 205 at the client 101, and determines if the received GUID 203 is associated with a subscribed user and what the subscribed service(s) are. If the received GUID 203 is associated with a subscribed user, the online service provider provides access to all of the subscribed online services 110-111 associated with the GUID 203 without requiring the user to provide a logon Id and password.

The online service provider **102** associates the GUID **203** of the user **100** with any number of online services **110-111** depending upon the online services selected by the user **100**. Three online services are shown in **Fig. 2**; however, it should be appreciated by those skilled in the art that the number of online services may be any number of online services, which an online service provider may provide.

In Fig. 2, having previously subscribed with the online service provider 102, the user 100 communicates with the web site 201 of the online service provider 102 through

the browser application program 202 on the client 101. In turn, the online service provider 102 receives the GUID 203 from the client 101 and facilitates access to the online services 110-111 by matching the received GUID 203 with the online services associated with the GUID 203.

As a result, under the invention, a user is not required to manage a logon ld and password pair in order to utilize and access several online services.

Figures 3a and 3b illustrate an alternate embodiment of the invention where one or more users from selected ones of different clients may access and utilize one or more online services through an online service provider without having to manage logon ld and password pairs, in accordance with the invention. In the illustrated embodiment, because an identifier, such as a GUID, is associated with the online service(s) selected by the user(s), one or more users may access one or more online services without regard for a particular client, i.e., roaming capability is provided to the one or more users allowing the access and utilization of one or more services from any client in any location.

In Fig. 3a, a first user 300 and a second user 305 are in communication with the online service provider 102 through the network 104. Also shown in Fig. 3a, are a first client 301 and a second client 306, each of which may be in different locations. Also shown in Fig. 3a, is an email service provider 310 in communication, through the network 104, with the online service provider 102 and the first and second users 300 and 305 through their respective first and second clients 301 and 306. The email service provider may be any email service provider such as, but not limited to, Hotmail®. The second user 305 may or may not be in communication with the first user

300. Additionally, as discussed with respect to Fig. 2, since the online service provider 102 offers several online services 110-111, the first user 300 and the second user 305 may select to access different online services 110-111, for example, the first user 300 may select billing masking service 111, while the second user 305 may select both services 110-111.

As discussed with respect to Fig. 2, the first user 300 and the second user 305 subscribe with the online service provider 102 via browser application programs 304 included within each client. In the embodiment shown in Fig. 3a, the first user 300 fills in the fields of the web site 350 of the online service provider 102 to subscribe with the online service provider 102. Shown in the embodiment of Fig. 3a, the online service provider 102 determines if a request for roaming capability is received from any of the users by detecting whether or not the roaming request field 351 is filled in by the user(s). Shown in Fig. 3a, the roaming request field 351 is a check box; however, it should be appreciated by those skilled in the art that the field may be any type of field to be filled in known in the art.

In **Fig. 3a**, the online service provider **102** receives the request for roaming capability from the first user **300**, and as will be described in further detail below, the online service provider **102** facilitates the roaming capability for the first user **300** by utilizing the GUID of the first client **301**, in accordance with the invention.

As shown in **Fig. 3a**, the online service provider **102** receives the subscription data from the first user **300** and the second user **305**. Included within the subscription data is a first GUID **320** corresponding to the first client **301** and a second GUID **321** corresponding to the second client **306**. Included within the request for roaming

capability from the first user **300**, is information regarding the subscribed services utilized by the first user **300**.

As discussed with respect to **Fig. 2**, included within the online service provider is a data structure suitable for use to store data associated with facilitating access to several online services by the online service provider **102**. Here again, the data structure may be a table **330** including a number of columns **331-335** for storing various information associated with one or more users. In particular, a column for a request of roaming capability **334** and a column for email addresses **335** associated with request for roaming capability column **334**.

Shown in **Fig. 3a**, is a GUID column **332** corresponding to one or more users, with each user having a different GUID. Additionally, online service columns **333** for the online services selected by the one or more users is shown corresponding to one or more users. As shown in table **330**, the online service provider **102** associates the first GUID **320** with the billing masking service **111**, selected by the first user **300**, and the online service provider **102** associates the second GUID **321** with both of the online services **110-111**, selected by the second user **305**. Even though two users are shown, it should be appreciated by those skilled in the art that the number of users and GUIDs may be several according to the number of users subscribed with the online service provider.

In order to facilitate roaming capability of the first user **300** utilizing the GUIDs, the online service provider **102** sends the first GUID **320** from the GUID column **332** corresponding to the first user **300**, along with a uniform resource locator (URL) of the online service provider **102** to connect to the web site **201** of the online service provider

**102**, to the email address **345** (e.g., a Hotmail® email account) specified by the first user **300** in email address column **335**.

Referring now to **Fig. 3b**, the first user **300** leaves the first client **301** and moves to the location of the second client **306**. Once at the second client **306**, the first user **300** retrieves email from the email service **310**. The first user may retrieve email from the email service **310** by any methods known in the art, such as but not limited to, using the POP protocol, or through a web service.

The first user 300 at the second client 306 receives the email from the online service provider 102, containing the first GUID 320 corresponding to the first user 300 and the URL to the web site 201 of the online service provider 102. Once the first user 300 at the second client 306 receives the email, the first user 300 "clicks" on the URL to the online service provider web site 201 and requests access to online service by communicating with the web site 201. Because the URL contains the first GUID 320 of the first user 300, the first user 300 is able to access all of the online credit card service 110 from the device of second client 306 without providing a logon Id and password pair to the online service provider 102, including the user's configuration setting. The URL and the GUID are stored in the received email.

Optionally, if the first user **300** intends to utilize the device of second client **306** for a period of time, the first user **300** may request that the first GUID **320** be deposited on the browser application program **304** of the second client **306** as discussed with respect to **Fig. 2**. The deposited GUID may be removed before the first user **300** moves to another client device (not shown).

As those skilled in the art would appreciate, as long as the first user **300** leaves the email with the GUID in the email received device, the first user **300** may roam to another device, repeat the process, and have access to his/her subscribed services, including his/her preference on the manner the services are rendered.

As a result, a user is able roam from one client to another client and still benefit from the ability to access and utilize several online services without the need for a logon ld and password pair.

Additionally, if a client of a user, for whatever reasons, has to be reconfigured, under the invention, the user is still able to access online services (including his/her preferred configurations) through an online service provider without the need to provide a logon Id and password pair. Similar to the earlier described roaming scenario, upon reconfiguring the user's machine to a level of operation that includes the ability to access the email service having the email containing the GUID and the URL of the web site of the online service provider, the user accesses the email service and retrieves the email from the email service. Thereafter, the user is able to proceed to access his/her subscribed online services, through his/her reconfigured client, in the same manner described earlier for the roaming scenario.

Figure 4 is a flow chart according to one embodiment of the invention, illustrating a client subscribing with an online service provider for accessing one or more online services without the need for a logon Id and password pair with the roaming capability.

The first illustrated operation is the user initializing **400** the computing device. It is assumed that initializing includes all steps required to boot, wake from idle state, or otherwise start the computing device and configure it for accessing online services.

Assume that the computing device is a desktop personal computer executing the Microsoft Windows® operating system. After initialization, the user loads **402** a communication program through which to access online services.

It will appreciated that a number of environments may be used to be implement the communication program. For example, a dedicated / custom application program may be designed to access online services over a network. Alternatively, the communication program can be built using communication features provided by Internet web browser products, such as Microsoft Internet Explorer™, Netscape Navigator™, or Opera™. In this latter environment, the communication may be implemented in one of, or a combination of, Java, JavaScript, JavaBeans, ActiveX, Visual Basic, HTML, DHTML, or other Internet related programming "languages". It is assumed herein that the communication program is based on an Internet browser, and that traditional Internet related communication protocols (e.g., TCP/IP, http, etc.) are used to communicate online service providers over the Internet. As discussed with respect to Fig. 2-3b, the online service provider provides a web address to which a client can connect to access online services provided by the online service provider.

After communication program initialization, the computing device is used to subscribe **404** the user with a web site maintained by a online service provider. Note, however, that even though the illustrated embodiment requires subscription, it will appreciated that in other embodiment, such subscription need not occur first, or at all. To subscribe, the computing device contacts **406** the web site. In response the web site sends an acknowledgment **408**. Since an Internet browser is assumed in use, the contact is by way of directing the browser to an appropriate receiving port monitored by

a web server of the online service provider. It is assumed that port 80, the traditional Internet communication port, is used for communication. In the web browser context, acknowledgment can be determined by receiving a "home page" or start page from the online service provider's web server.

If no acknowledgment is received, then a subscription error has occurred and processing of this subscription halts **412**. If acknowledgment is received, then the client tells the online service provider that it is interested in subscribing with the online service provider.

In one embodiment, the subscription process is automated, where the online service provider server (not shown) is configured to receive a subscription command from the client, and in response, the online service provider sends the client subscription forms to complete. For example, in response to the subscription command, an HTML form (or equivalent structure) containing fields for the user's name, address, request for roaming capability, email address, and so forth, is sent 414 to the client. This form (or equivalent structure) is completed 416 and returned 418 to an online service provider. In response to receiving the subscription data, the online service provider processes the received subscription data by correlating and associating an identifier of the user and the client, included within the received subscription data, with online service(s) selected by the user 420.

Completion of the form can be automated, through automated parsing of the form to identify various fields to fill out. In one embodiment, the extensible markup language (XML) is used to encode forms with semantic meaning to facilitate automatic interpreting and completing of a form. In an alternate embodiment, the user is allowed

to review and complete a form with data known to the user, or the user can be provided with an opportunity to review and change a form completed by the computing device. In another embodiment, a special communication port, analogous to browser port 80, is used to send and receive subscription data.

Figure 5 illustrates the operational flow of the relevant aspects of the online service provider 102 for facilitating access to online services requiring logon configurations and roam from one device to another without having to manage several logon lds and passwords, and configurations. As illustrated in Fig. 5, an online service provider receives a request from a client to access an online service, 510. Comprising the request is a globally unique identifier (GUID) of the client.

In response to the received GUID, the online service provider determines if the GUID is associated with a subscriber, **520**. The online service provider associates the GUID of the client with the online services of the identified user based at least upon subscription data previously received when a user subscribed with the online service provider.

If the online service provider determines that the GUID is associated with a user, the online service provider facilitates access to the subscribed online service of the user without requiring logon Id and password pair, **530**. Accordingly, a user can access the online services from other locations as well (i.e., roaming), or from a reconfiguration machine as well, thereby significantly improving the user friendliness of online service provider, and the user's productivity.

Figure 6 illustrates an example server suitable for use for online service provider 102 of Fig. 1, in accordance with one embodiment. As shown, server 600 includes one

or more processors 602 and system memory 606. Additionally, server 600 includes mass storage devices 607 (such as diskette, hard drive, CDROM and so forth), GPIO 608 (for interfacing with I/O devices such as keyboard, cursor control and so forth) and communication interfaces 612 (such as network interface cards, modems and so forth). The elements are coupled to each other via system bus 614, which represents one or more buses. In the case of multiple buses, they are bridged by one or more bus bridges (not shown). Each of these elements perform its conventional functions known in the art. In particular, system memory 604 and mass storage 606 are employed to store a working copy and a permanent copy of the programming instructions implementing access to online services 110-111. Except for its use to host the novel online service provider of the present invention, the constitution of these elements 602-614 are known, and accordingly will not be further described.

Certain embodiments may include additional components, may not require all of the above components, or may combine one or more components. Those skilled in the art will be familiar with a variety of alternative implementations.

In one embodiment, the invention, as described above, is implemented using one or more computing devices such as the server of **Fig. 6**. In one embodiment, the invention is implemented as software routines executed by one or more execution units within the server(s). For a given server, the software routines can be stored on a storage device, such as system memory **620**.

In one embodiment, the software routines are written in the C programming language. It should be appreciated that the software routines may be implemented in any of a wide variety of programming languages. In alternate embodiments, the

invention is implemented in discrete hardware or firmware. For example, one or more application specific integrated circuit (ASICs) could be programmed with one or more of the above described functions of the server 600. In another example, one or more functions of the server 600 could be implemented in one or more ASICs on additional circuit boards, and the circuit boards could be inserted into the device(s) described above. In another example, field programmable gate arrays (FPGAs) or static programmable gate arrays (SPGAs) could be used to implement one or more functions of the invention. In yet another example, a combination of hardware and software could be used to implement one or more functions of the invention.

Accordingly, methods and apparatuses for a user to access online services requiring logon configurations and roam from one device to another without having to manage several logon configurations is described. While the present invention has been described in terms of the above illustrated embodiments, those skilled in the art will recognize that the invention is not limited to the embodiments described. The present invention can be practiced with modification and alteration within the spirit and scope of the appended claims. Thus, the description is to be regarded as illustrative instead of restrictive on the present invention.
